

ABSTRACT OF THE DISCLOSURE

A child safety seat comprises a seat body having opposed side wall portions, a retention harness comprising opposed harness side portions, and a retention member carried on each side wall portion to connect and hold the latch of each harness side portion in a laterally spaced position from the other latch of the other harness side portion, which position is typically elevated relative to their position of use. This facilitates the placement of a child into the safety seat prior to latching the retention harness latches together.
